Process Synchronization

Chapter 5: Process Synchronization

- Background
- The Critical-Section Problem
- Peterson's Solution
- Synchronization Hardware
- Mutex Locks
- Semaphores
- Classic Problems of Synchronization
- Monitors
- Synchronization Examples
- Alternative Approaches

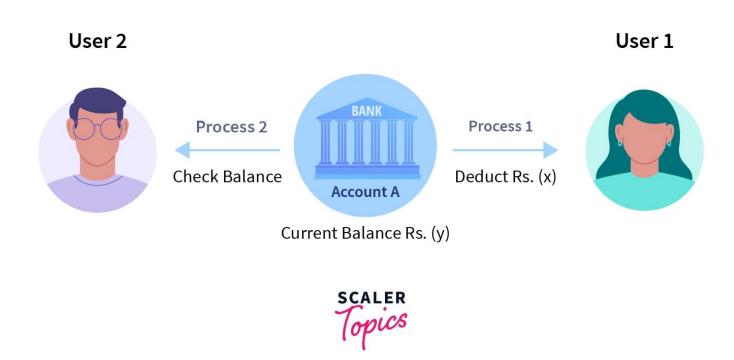

Objectives

- □ To present the concept of process synchronization.
- ☐ To introduce the critical-section problem, whose solutions can be used to ensure the consistency of shared data
- To present both software and hardware solutions of the critical-section problem
- To examine several classical process-synchronization problems
- To explore several tools that are used to solve process synchronization problems

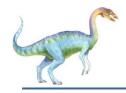

Example

Example: Train Booking via IRCTC

Difficulties of Concurrency

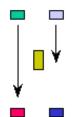

- Sharing of global resources coordinated access to shared resources
- Operating system managing the allocation of resources optimally do we know the future behaviour (needed resources) of processes?
- Difficult to locate programming errors

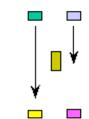

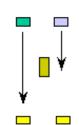

Independent vs. Cooperating Processes

- Independent
 - no shared state
 - deterministic
 - each process can proceed at arbitrary rate

- Cooperating
 - Shared state
 - like a common variable
 - non-deterministic execution
 - hard to reproduce, and subject to race conditions

A Simple Example for Two Processes

Process P1

Process P2

chin = getchar();

•

chout = chin;

putchar(chout);

.

-

chin = getchar();

•

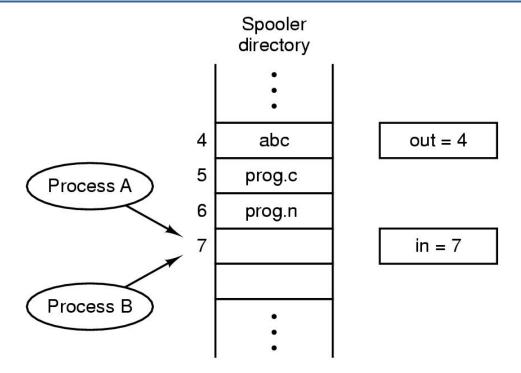

chout = chin;

•

putchar(chout);

Race Conditions

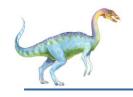

- Two processes want to access shared memory at the same time.
 - The final result depends on who runs precisely when.
- A Race condition is a scenario that occurs in a multithreaded environment due to multiple threads sharing the same resource or executing the same piece of code.

Critical Section Problem

- □ Consider system of n processes $\{p_0, p_1, \dots p_{n-1}\}$
- □ Each process has critical section segment of code
 - Process may be changing common variables, updating table, writing file, etc
 - When one process in critical section, no other may be in its critical section
- Critical section problem is to design protocol to solve this
- Each process must ask permission to enter critical section in entry section, may follow critical section with exit section, then remainder section

Critical Section

☐ General structure of process **P**_i

```
do {
    entry section
    critical section

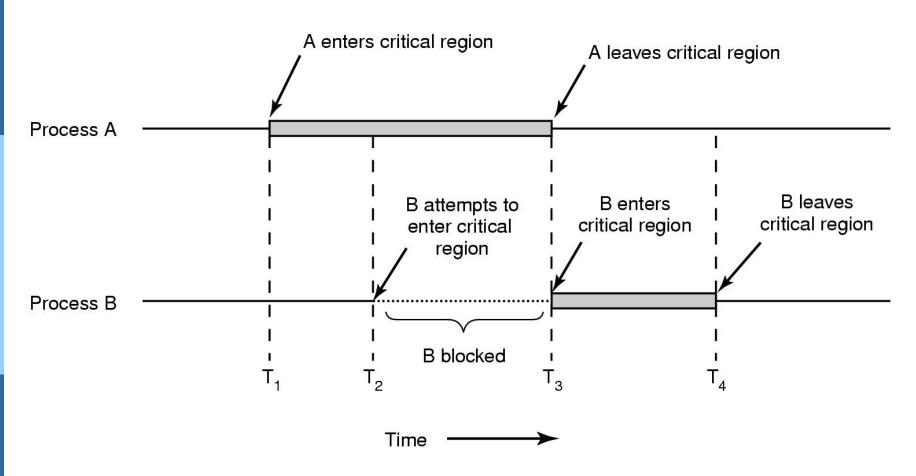

exit section

remainder section
} while (true);
```

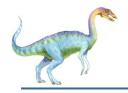

Critical Regions

Mutual exclusion using critical regions

Solution to Critical-Section Problem

- 1. Mutual Exclusion If process P_i is executing in its critical section, then no other processes can be executing in their critical sections
- 2. **Progress** If no process is executing in its critical section and there exist some processes that wish to enter their critical section, then the selection of the processes that will enter the critical section next cannot be postponed indefinitely
- 3. **Bounded Waiting** A bound must exist on the number of times that other processes are allowed to enter their critical sections after a process has made a request to enter its critical section and before that request is granted
 - Assume that each process executes at a nonzero speed
 - No assumption concerning relative speed of the n processes

Critical-Section Handling in OS

Two approaches depending on if kernel is preemptive or non-preemptive

- Preemptive allows preemption of process when running in kernel mode
- Non-preemptive runs until exits kernel mode, blocks, or voluntarily yields CPU
 - Essentially free of race conditions in kernel mode

Algorithm for Process P_i

```
do {
    while (turn == j);
        critical section
    turn = j;
        remainder section
} while (true);
```

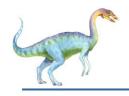

Peterson's Solution

- Good algorithmic description of solving the problem
- Two process solution
- Assume that the **load** and **store** machine-language instructions are atomic; that is, cannot be interrupted
- ☐ The two processes share two variables:
 - □ int turn;
 - □ Boolean flag[2]
- The variable turn indicates whose turn it is to enter the critical section
- The flag array is used to indicate if a process is ready to enter the critical section. flag[i] = true implies that process P_i is ready!

Algorithm for Process Pi

do {

```
flag[i] = true;
turn = j;
while (flag[j] && turn = = j);
```

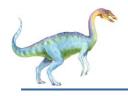

critical section

```
flag[i] = false;
```

remainder section

} while (true);

Algorithm for Process Pi

do {

```
flag[j] = true;
turn = i;
while (flag[i] && turn = = i);
```

critical section

```
flag[j] = false;
```

remainder section

} while (true);

2 Process: Pi and Pj

For process Pi

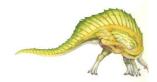

For process Pj

```
do {
    flag[i] = true;
    turn = j;
    while (flag[j] && turn = = j);
        critical section
    flag[i] = false;
        remainder section
    } while (true);
```

```
do {
    flag[j] = true;
    turn = i;
    while (flag[i] && turn = = i);

        critical section
    flag[j] = false;

        remainder section
    } while (true);
```

Peterson's Solution (Cont.)

- Provable that the three CS requirement are met:
 - 1. Mutual exclusion is preserved

```
P<sub>i</sub> enters CS only if:
```

```
either flag[j] = false or turn = i
```

- 2. Progress requirement is satisfied
- 3. Bounded-waiting requirement is met

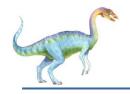

Synchronization Hardware

- Many systems provide hardware support for implementing the critical section code.
- All solutions below based on idea of locking
 - Protecting critical regions via locks
- Uniprocessors could disable interrupts
 - Currently running code would execute without preemption
 - Generally too inefficient on multiprocessor systems
 - Operating systems using this not broadly scalable
- Modern machines provide special atomic hardware instructions
 - Atomic = non-interruptible
 - Either test memory word and set value
 - Or swap contents of two memory words

Solution to Critical-section Problem Using Locks

test_and_set Instruction

Definition:

```
boolean test_and_set (boolean *target)
{
    boolean rv = *target;
    *target = TRUE;
    return rv:
}
```

- 1. Executed atomically
- 2. Returns the original value of passed parameter
- 3. Set the new value of passed parameter to "TRUE".

Solution using test_and_set()

- Shared Boolean variable lock, initialized to FALSE
- Solution:

compare_and_swap Instruction

Definition:

```
int compare _and_swap(int *value, int expected, int new_value) {
   int temp = *value;

   if (*value == expected)
        *value = new_value;

   return temp;
}
```

- 1. Executed atomically
- 2. Returns the original value of passed parameter "value"
- 3. Set the variable "value" the value of the passed parameter "new_value" but only if "value" =="expected". That is, the swap takes place only under this condition.

Solution using compare_and_swap

- Shared integer "lock" initialized to 0;
- Solution:

```
do {
    while (compare_and_swap(&lock, 0, 1) != 0)
    ; /* do nothing */
    /* critical section */
lock = 0;
    /* remainder section */
} while (true);
```

Bounded-waiting Mutual Exclusion with test_and_set

```
do {
   waiting[i] = true;
   key = true;
   while (waiting[i] && key)
      key = test and set(&lock);
   waiting[i] = false;
   /* critical section */
   j = (i + 1) % n;
   while ((j != i) && !waiting[j])
      i = (i + 1) % n;
   if (j == i)
      lock = false;
   else
      waiting[j] = false;
   /* remainder section */
} while (true);
```

Mutex Locks

- Previous solutions are complicated and generally inaccessible to application programmers
- OS designers build software tools to solve critical section problem
- Simplest is mutex lock
- Protect a critical section by first acquire() a lock then release() the lock
 - Boolean variable indicating if lock is available or not
- Calls to acquire() and release() must be atomic
 - Usually implemented via hardware atomic instructions
- But this solution requires busy waiting
 - This lock therefore called a spinlock

acquire() and release()

```
acquire() {
while (!available)
          ; /* busy wait */
       available = false;
    release() {
П
       available = true;
do {
    acquire lock
       critical section
    release lock
      remainder section
 } while (true);
```

Semaphore

- Synchronization tool that provides more sophisticated ways (than Mutex locks) for process to synchronize their activities.
- □ Semaphore S integer variable
- Can only be accessed via two indivisible (atomic) operations
 - uait() and signal()
 - Originally called P() and V()

Semaphore

Definition of the wait() operation

Definition of the **signal() operation**

```
wait(S) {
    while (S <= 0)
    ; //busy wait
    S--;</pre>
```

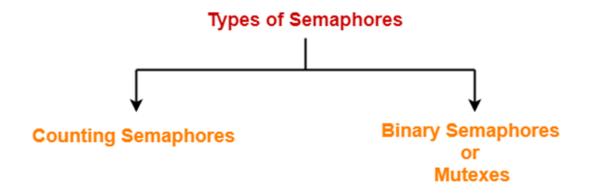

```
signal(S) {
    S++;
}
```

Types of Semaphore

- Counting semaphore integer value can range over an unrestricted domain
- Binary semaphore integer value can range only between 0 and 1
 - Same as a mutex lock

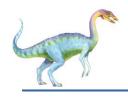

Semaphore Usage

- Can solve various synchronization problems
- Consider P₁ and P₂ that require S₁ to happen before S₂
 Create a semaphore "synch" initialized to 0
 P1:

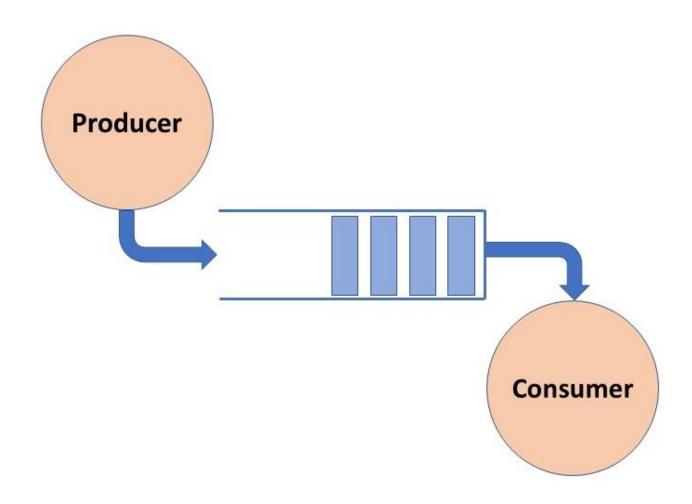

```
S<sub>1</sub>;
signal(synch);
P2:
wait(synch);
S<sub>2</sub>;
```

Can implement a counting semaphore S as a binary semaphore

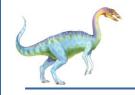

Producer Consumer Problem

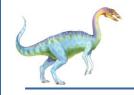

Producer

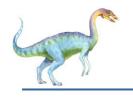

Consumer

```
while (true) {
    while (counter == 0)
        ; /* do nothing */
    next_consumed = buffer[out];
    out = (out + 1) % BUFFER_SIZE;
    counter--;
    /* consume the item in next consumed */
}
```

Race Condition

counter++ could be implemented as

```
register1 = counter
register1 = register1 + 1
counter = register1
```

counter-- could be implemented as

```
register2 = counter
register2 = register2 - 1
counter = register2
```

Consider this execution interleaving with "count = 5" initially:

```
S0: producer execute register1 = counter {register1 = 5}

S1: producer execute register1 = register1 + 1 {register1 = 6}

S2: consumer execute register2 = counter {register2 = 5}

S3: consumer execute register2 = register2 - 1 {register2 = 4}

S4: producer execute counter = register1 {counter = 6}

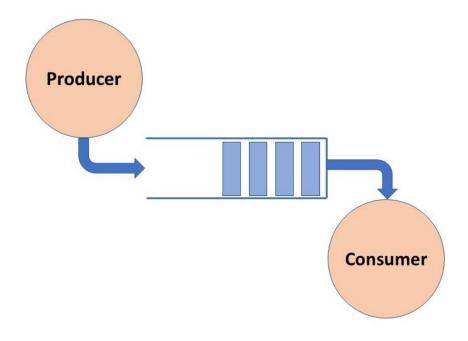

S5: consumer execute counter = register2 {counter = 4}
```

Producer-Consumer problem

- Bounded Buffer problem
- The problem is defined as follows: there is a fixed-size buffer and a Producer process, and a Consumer process.
- The Producer process creates an item and adds it to the shared buffer. The Consumer process takes items out of the shared buffer and "consumes" them.

Solution using semaphore

Problem Statement –

We have a buffer of fixed size. A producer can produce an item and can place in the buffer. A consumer can pick items and can consume them. We need to ensure that when a producer is placing an item in the buffer, then at the same time consumer should not consume any item. In this problem, buffer is the critical section.

Initialization of semaphores -

mutex = 1

Full = 0 // Initially, all slots are empty. Thus full slots are 0
Empty = n // All slots are empty initially

```
Solution for Consumer –
Solution for Producer –
do{
                                     do{
//produce an item
                                     //produce an item
wait(empty);
                                     wait(empty);
wait(mutex);
                                     wait(mutex);
//place in buffer
                                     //place in buffer
signal(mutex);
                                     signal(mutex);
signal(full);
                                     signal(full);
}while(true)
                                     }while(true)
```

PRACTICE PROBLEMS: GATE CS

□ Each process Pi, i = 1, 2, ..., 9 is coded as follows-

```
repeat
P(mutex)
{ Critical Section }
V(mutex)
```

Forever

The code for P_{10} is identical except that it uses V(mutex) in place of P(mutex). What is the largest number of processes that can be inside the critical section at any moment?

- a) 1
- b) 2
- c) 3
- d) None of these

A shared variable x, initialized to zero, is operated on by four concurrent processes W, X, Y, Z as follows. Each of the processes W and X reads x from memory, increments by one, stores it to memory, and then terminates. Each of the processes Y and Z reads x from memory, decrements by two, stores it to memory, and then terminates. Each process before reading x invokes the P operation (i.e., wait) on a counting semaphore S and invokes the V operation (i.e., signal) on the semaphore S after storing x to memory. Semaphore S is initialized to two. What is the maximum possible value of x after all processes complete execution?

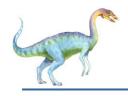

Semaphore Implementation

- Must guarantee that no two processes can execute the wait() and signal() on the same semaphore at the same time
- Thus, the implementation becomes the critical section problem where the wait and signal code are placed in the critical section
 - Could now have busy waiting in critical section implementation
 - But implementation code is short
 - Little busy waiting if critical section rarely occupied
- Note that applications may spend lots of time in critical sections and therefore this is not a good solution

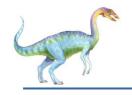

Semaphore Implementation with no Busy waiting

- With each semaphore there is an associated waiting queue
- Each entry in a waiting queue has two data items:
 - value (of type integer)
 - pointer to next record in the list
- Two operations:
 - block place the process invoking the operation on the appropriate waiting queue
 - wakeup remove one of processes in the waiting queue and place it in the ready queue

```
typedef struct{
  int value;
  struct process *list;
} semaphore;
```

Implementation with no Busy waiting (Cont.)

```
wait(semaphore *S) {
   S->value--;
   if (S->value < 0) {
      add this process to S->list;
      block();
signal(semaphore *S) {
   S->value++;
   if (S->value <= 0) {
      remove a process P from S->list;
      wakeup(P);
```

Deadlock and Starvation

- Deadlock two or more processes are waiting indefinitely for an event that can be caused by only one of the waiting processes
- □ Let S and Q be two semaphores initialized to 1

```
P_0 P_1 wait(S); wait(Q); wait(Q); wait(S); ... signal(S); signal(Q); signal(S);
```

- ☐ Starvation indefinite blocking
 - A process may never be removed from the semaphore queue in which it is suspended
- Priority Inversion Scheduling problem when lower-priority process holds a lock needed by higher-priority process
 - Solved via priority-inheritance protocol

Classical Problems of Synchronization

- Classical problems used to test newly-proposed synchronization schemes
 - Bounded-Buffer Problem
 - Readers and Writers Problem
 - Dining-Philosophers Problem

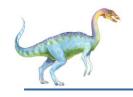

Bounded-Buffer Problem

- □ n buffers, each can hold one item
- Semaphore mutex initialized to the value 1
- Semaphore **full** initialized to the value 0
- Semaphore empty initialized to the value n

Bounded Buffer Problem (Cont.)

The structure of the producer process

```
do {
      /* produce an item in next produced */
   wait(empty);
   wait(mutex);
      /* add next produced to the buffer */
   signal(mutex);
   signal(full);
} while (true);
```

Bounded Buffer Problem (Cont.)

The structure of the consumer process

```
Do {
   wait(full);
   wait(mutex);
    /* remove an item from buffer to next consumed */
    signal(mutex);
    signal(empty);
    /* consume the item in next consumed */
} while (true);
```

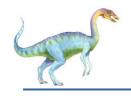

Readers-Writers Problem

- A data set is shared among a number of concurrent processes
 - Readers only read the data set; they do not perform any updates
 - Writers can both read and write
- Problem allow multiple readers to read at the same time
 - Only one single writer can access the shared data at the same time
- Several variations of how readers and writers are considered all involve some form of priorities
- Shared Data
 - Data set
 - Semaphore rw mutex initialized to 1
 - Semaphore mutex initialized to 1
 - Integer read_count initialized to 0

Readers-Writers Problem (Cont.)

☐ The structure of a writer process

Readers-Writers Problem (Cont.)

The structure of a reader process

```
do {
       wait(mutex);
       read count++;
       if (read count == 1)
       wait(rw mutex);
    signal (mutex);
       /* reading is performed */
    wait(mutex);
       read count--;
       if (read count == 0)
    signal(rw mutex);
    signal(mutex);
} while (true);
```

Readers-Writers Problem Variations

- First variation no reader kept waiting unless writer has permission to use shared object
- Second variation once writer is ready, it performs the write ASAP
- Both may have starvation leading to even more variations
- Problem is solved on some systems by kernel providing reader-writer locks

Dining-Philosophers Problem

- Philosophers spend their lives alternating thinking and eating
- Don't interact with their neighbors, occasionally try to pick up 2 chopsticks (one at a time) to eat from bowl
 - Need both to eat, then release both when done
- In the case of 5 philosophers
 - Shared data
 - Bowl of rice (data set)
 - Semaphore chopstick [5] initialized to 1

Dining-Philosophers Problem Algorithm

```
The structure of Philosopher i:
       do {
            wait (chopstick[i] );
            wait (chopStick[ (i + 1) % 5] );
                         // eat
            signal (chopstick[i] );
             signal (chopstick[ (i + 1) % 5] );
                              think
       } while (TRUE);
    What is the problem with this algorithm?
П
```

Dining-Philosophers Problem Algorithm (Cont.)

Deadlock handling

- Allow at most 4 philosophers to be sitting simultaneously at the table.
- Allow a philosopher to pick up the forks only if both are available (picking must be done in a critical section.
- Use an asymmetric solution -- an odd-numbered philosopher picks up first the left chopstick and then the right chopstick. Even-numbered philosopher picks up first the right chopstick and then the left chopstick.

Problems with Semaphores

- Incorrect use of semaphore operations:
 - signal (mutex) wait (mutex)
 - wait (mutex) ... wait (mutex)
 - Omitting of wait (mutex) or signal (mutex) (or both)
- Deadlock and starvation are possible.

Monitors

- A high-level abstraction that provides a convenient and effective mechanism for process synchronization
- Abstract data type, internal variables only accessible by code within the procedure
- Only one process may be active within the monitor at a time
- But not powerful enough to model some synchronization schemes

```
monitor monitor-name
{
    // shared variable declarations
    procedure P1 (...) { ..... }

    procedure Pn (...) { ......}

    Initialization code (...) { ... }
}
```

Schematic view of a Monitor

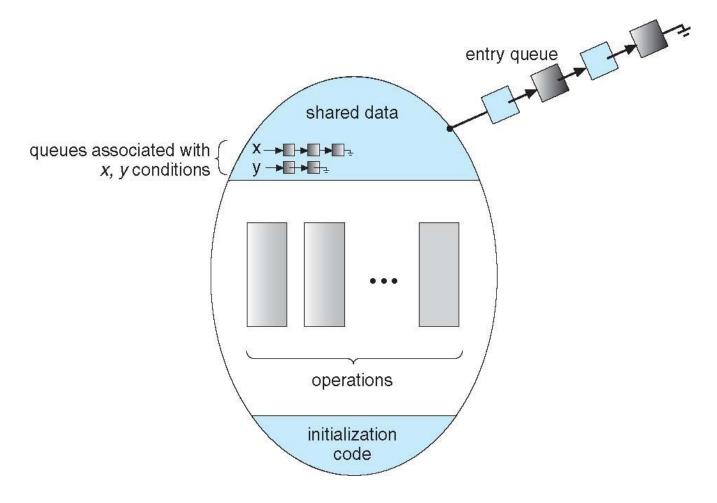

Condition Variables

- condition x, y;
- □ Two operations are allowed on a condition variable:
 - x.wait() a process that invokes the operation is suspended until x.signal()
 - material = x.signal() resumes one of processes (if any) that invoked x.wait()
 - If no x.wait() on the variable, then it has no effect on the variable

Monitor with Condition Variables

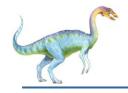

Condition Variables Choices

- If process P invokes x.signal(), and process Q is suspended in x.wait(), what should happen next?
 - Both Q and P cannot execute in paralel. If Q is resumed, then P must wait
- Options include
 - Signal and wait P waits until Q either leaves the monitor or it waits for another condition
 - Signal and continue Q waits until P either leaves the monitor or it waits for another condition
 - □ Both have pros and cons language implementer can decide
 - Monitors implemented in Concurrent Pascal compromise
 - P executing signal immediately leaves the monitor, Q is resumed
 - Implemented in other languages including Mesa, C#, Java

Monitor Solution to Dining Philosophers

```
monitor DiningPhilosophers
  enum { THINKING; HUNGRY, EATING) state [5];
  condition self [5];
  void pickup (int i) {
          state[i] = HUNGRY;
          test(i);
          if (state[i] != EATING) self[i].wait;
   void putdown (int i) {
          state[i] = THINKING;
                   // test left and right neighbors
           test((i + 4) % 5);
           test((i + 1) % 5);
```

Solution to Dining Philosophers (Cont.)

```
void test (int i) {
        if ((state[(i + 4) % 5] != EATING) &&
        (state[i] == HUNGRY) &&
        (state[(i + 1) % 5] != EATING)) 
             state[i] = EATING;
        self[i].signal ();
    initialization code() {
       for (int i = 0; i < 5; i++)
       state[i] = THINKING;
```

Solution to Dining Philosophers (Cont.)

Each philosopher i invokes the operations pickup() and putdown() in the following sequence:

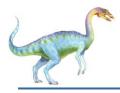

```
DiningPhilosophers.pickup(i);
```

EAT

```
DiningPhilosophers.putdown(i);
```

No deadlock, but starvation is possible

Monitor Implementation Using Semaphores

Variables

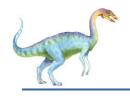

```
semaphore mutex; // (initially = 1)
semaphore next; // (initially = 0)
int next_count = 0;
```

Each procedure F will be replaced by

```
wait(mutex);
...
body of F;
...
if (next_count > 0)
  signal(next)
else
  signal(mutex);
```

Mutual exclusion within a monitor is ensured

Monitor Implementation – Condition Variables

For each condition variable **x**, we have:

```
semaphore x_sem; // (initially = 0)
int x_count = 0;
```

The operation x.wait can be implemented as:

```
x_count++;
if (next_count > 0)
    signal(next);
else
    signal(mutex);
wait(x_sem);
x count--;
```

Monitor Implementation (Cont.)

The operation x.signal can be implemented as:

```
if (x_count > 0) {
   next_count++;
   signal(x_sem);
   wait(next);
   next_count--;
}
```

Resuming Processes within a Monitor

- If several processes queued on condition x, and x.signal() executed, which should be resumed?
- FCFS frequently not adequate
- conditional-wait construct of the form x.wait(c)
 - Where c is priority number
 - Process with lowest number (highest priority) is scheduled next

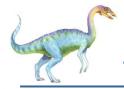

Single Resource allocation

Allocate a single resource among competing processes using priority numbers that specify the maximum time a process plans to use the resource

```
R.acquire(t);
...
access the resurce;
...
R.release;
```

Where R is an instance of type ResourceAllocator

A Monitor to Allocate Single Resource

```
monitor ResourceAllocator
   boolean busy;
   condition x;
   void acquire(int time) {
            if (busy)
              x.wait(time);
           busy = TRUE;
   void release() {
           busy = FALSE;
            x.signal();
initialization code() {
    busy = FALSE;
```

Synchronization Examples

- Solaris
- Windows
- Linux
- Pthreads

Solaris Synchronization

- Implements a variety of locks to support multitasking, multithreading (including real-time threads), and multiprocessing
- Uses adaptive mutexes for efficiency when protecting data from short code segments
 - Starts as a standard semaphore spin-lock
 - If lock held, and by a thread running on another CPU, spins
 - If lock held by non-run-state thread, block and sleep waiting for signal of lock being released
- Uses condition variables
- Uses readers-writers locks when longer sections of code need access to data
- Uses turnstiles to order the list of threads waiting to acquire either an adaptive mutex or reader-writer lock
 - Turnstiles are per-lock-holding-thread, not per-object
- Priority-inheritance per-turnstile gives the running thread the highest of the priorities of the threads in its turnstile

Windows Synchronization

- Uses interrupt masks to protect access to global resources on uniprocessor systems
- Uses spinlocks on multiprocessor systems
 - Spinlocking-thread will never be preempted
- Also provides dispatcher objects user-land which may act mutexes, semaphores, events, and timers
 - Events
 - An event acts much like a condition variable
 - Timers notify one or more thread when time expired
 - Dispatcher objects either signaled-state (object available) or non-signaled state (thread will block)

Linux Synchronization

- Linux:
 - Prior to kernel Version 2.6, disables interrupts to implement short critical sections
 - Version 2.6 and later, fully preemptive
- Linux provides:
 - Semaphores
 - atomic integers
 - spinlocks
 - reader-writer versions of both
- On single-cpu system, spinlocks replaced by enabling and disabling kernel preemption

Pthreads Synchronization

- Pthreads API is OS-independent
- It provides:
 - mutex locks
 - condition variable
- Non-portable extensions include:
 - read-write locks
 - spinlocks

Alternative Approaches

- □ Transactional Memory
- OpenMP
- Functional Programming Languages

Transactional Memory

A memory transaction is a sequence of read-write operations to memory that are performed atomically.

```
void update()
{
    /* read/write memory */
}
```

OpenMP

OpenMP is a set of compiler directives and API that support parallel programming.

```
void update(int value)
{
    #pragma omp critical
    {
        count += value
    }
}
```

The code contained within the **#pragma omp critical** directive is treated as a critical section and performed atomically.

Functional Programming Languages

- ☐ Functional programming languages offer a different paradigm than procedural languages in that they do not maintain state.
- Variables are treated as immutable and cannot change state once they have been assigned a value.
- ☐ There is increasing interest in functional languages such as Erlang and Scala for their approach in handling data races.

End of Chapter 5
